

## Part IV Compound Library: Dynamic Application

### Introduction:

Car manufacturers have ask for a series of engine mounts with a stepwise increase of a property, the static stiffness for example, to tune the NVH behavior of a car. Normally the engineer would go in the warehouse and collect some parts, which may fit into the customers project. This has caused discussions about a **compound library**, which enables to serve the customer any time. Nobody had to search and collect anymore.

Specifically a compound library would make sense, if the static stiffness is varies, but the dynamic hardening is kept constant, beside other properties, like compression set, tensile for example.

This challenge is almost ideal to evaluate with AI based software like G<sup>raf</sup>Compounder, without a lot of trials and effort in the laboratory.

### Procedure:

For this demonstration, I selected a compound file based on EPDM. The file consists of some DoE (Design of Experiment), screenings and few Trial&Error data sets. The original purpose of the development was to investigate the service life of a round mount for vibration decoupling between the body and chassis. The main components of this data sets are as follows:

- EPDM C2 – 58 %, ENB – 5 %, VH Mooney grade
- Carbon Black range  
CB N550: 30 phr – 60 phr  
Perkasil KS 207 0 phr – 75 phr  
Paraffinic Oil 20 phr – 85 phr
- Accelerator System  
Sulfur / TMTD / CBS identicall for almost all data sets.

Evaluation of Data in the 2 D Diagram starts with the correlation analysis and discharge of data not fitting an estimated trendline to yield a correlation coefficient greater than 0,9. We have a good correlation between hardness and C<sub>stat</sub> (**Figure 1**) and we accept this data sets for further evaluation. (Remark: The value in the upper right corner is confirmed)

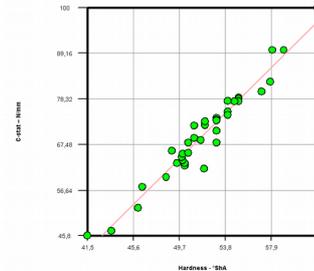

Figure 1: Hardness over C<sub>stat</sub>: Correlation coefficient 0,97.

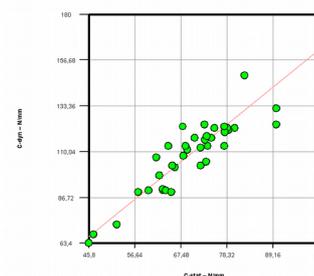

Figure 2: C<sub>dyn</sub> over C<sub>stat</sub>: correlation coefficient 0,91.

| Criteria:         |      |      |      |      |        |        |
|-------------------|------|------|------|------|--------|--------|
| Name              | Min  | Max  | From | To   | Weight | Trdoff |
| Loss Angle 23°C - | 3,7  | 7,5  |      |      |        |        |
| Loss Angle -25°C  | 16   | 22,3 |      |      |        |        |
| C-dyn - N/mm      | 63,4 | 180  | 92   | 92   | 50     |        |
| C-stat - N/mm     | 45,8 | 100  | 68   | 68   |        |        |
| Verhärtungsfaktor | 1,37 | 1,81 | 1,42 | 1,42 | 50     |        |

Table 1: Section of criteria window with targets and weights

In the criteria window the values are set for

- Hardening Factor (VHF):  
1,72 – in the first run  
1,42 – in the second run  
always with a weight of 50 (See **table 1** as an example)
- The  $C_{stat} / C_{dyn}$  pairs I selected using the Cdyn over Cstat Diagram (**Figure 2**).
  - Choose a  $C_{stat}$  value on the x-Axis and identify a  $C_{dyn}$  value on the y-axis.  
Just to be sure put a weight of 50 on the  $C_{dyn}$  value.
  - The results reported in **table 2**.
- Append the experimental mixture columns into the <Input data> window to visualize their location in the diagram (**Figure 3**).  
Finally we discard all original data sets and show the experimental  $G^{raf}$ Compounder data point alone, which are unconfirmed yet.

What should be done before we perform a confirmation experiment: Prove, whether results are logic and in line with experience.

For this we check the physicals of the compounds (**table 3**).

| VHF  | $C_{stat}$ | H-°ShA | TS-MPa | EB-% | C-Set-%<br>125°C/72h | $\Sigma$ -Filler<br>- phr | Oil<br>- phr |
|------|------------|--------|--------|------|----------------------|---------------------------|--------------|
| 1,72 | 98         | 61     | 15     | 480  | 40                   | 58                        | 36,2         |
| 1,72 | 90         | 58     | 16     | 535  | 45                   | 60                        | 43           |
| 1,72 | 80         | 56     | 14     | 525  | 43                   | 58                        | 47           |
| 1,72 | 68         | 52,5   | 13     | 551  | 45                   | 59                        | 58           |
| 1,72 | 62,5       | 51,2   | 12     | 585  | 47                   | 72                        | 62           |
| 1,42 | 90         | 58,4   | 11     | 455  | 47                   | 51                        | 22           |
| 1,42 | 80         | 55     | 9      | 430  | 43                   | 42,5                      | 30,8         |
| 1,42 | 62         | 50     | 7      | 405  | 44                   | 47                        | 43           |

### Conclusion:

- Data suggest, that Dynamic Hardening [VHF] is mainly dependend on filler content comparing both compound series.
- C-Set is almost unaffected
- $\tan\delta$  is 6° for the 1,72 VHF and 4° for the 1,42 VHF
- Regarding other basic physicals there is some room to meet specification targets, specifically the Hardness follow  $C_{stat}$ .
- $G^{raf}$ Compounder allows to provide parts designed as a compound library for NVH tuning of cars or any other machine
